# 1.0 INTRODUCTION

# 1.1 General

This Noise Monitoring Report is required to be prepared annually by Rule 1.2.4.2 in Part 11 of the Christchurch City Plan. The purpose of the report is to present the annual calculated noise contours and associated monitoring results which have been prepared to assess compliance with the City Plan noise standard for aircraft operations at the Airport. This report for the 2013 calendar year includes the calculated noise contours, noise measurement results and information on engine testing activity.

Christchurch International Airport is the main gateway to the South Island with current total aircraft movements of between90,000 to 100,000 per annum.

The total number of commercial aircraft movements for the 2013 calendar year was 71,715, as shown below. A summary of the movement data input to the INM computer model for producing the 2013 Aircraft Noise Contours is provided in section 2.1 of this report.

# 1.2 Noise Performance Standards – Aircraft Operations

The Christchurch City Plan refers to airport noise in a number of locations. Rule 11-1.3.6 refers to the Airport's requirement to not exceed 65 dB  $L_{dn}$  outside the airport noise contour shown in the City Plan (Volume 3, Part 2, Appendix 3 – 65 dB  $L_{dn}$  Airport Noise Monitoring contour - CIAL). The rule states:

"1.3.6 Aircraft Noise

# Critical Standard

CIAL shall manage the Christchurch International Airport so that the noise from aircraft operations does not exceed  $L_{dn}$  65 dBA outside the  $L_{dn}$  65 dBA airport noise contour shown in Appendix 3 to Part II.

Noise from aircraft operations shall be based on noise data from the Integrated Noise Model (INM) and records of actual aircraft operations at CIA. The noise level shall be calculated over the busiest three month period of the year.

Aircraft operations means:

- the landing and take off of aircraft at CIA
- aircraft flying along any flight path associated with a landing or take off at CIA

The following activities are excluded from the definition of Aircraft Operations:

- aircraft operating in an emergency for medical or national/civil defence reasons
- air shows
- military operations not associated with the Antarctic programme
- aircraft using the airport as an alternative to a scheduled airport elsewhere
- aircraft taxiing
- aircraft engine testing.

Exceedance by up to 1 dBA of the noise limit is permitted provided CIAL demonstrates at the request of, and to the satisfaction of, the Council that any such exceedance is due to atypical weather patterns."

The Christchurch Airport 65 dB L<sub>dn</sub> District Plan noise contour crosses over three different districts Waimakariri, Selwyn and Christchurch City. In 2007 a new set of District Plan noise contours were formulated, these contours have been implemented, and are operative in the Selwyn and Waimakariri District Plans. For Christchurch City, the Land Use Recovery Plan has adopted the new contours for land use planning purposes but the rule relating to airport noise control (rule 1.2.4.2) refers to the old District Plan noise contours. In view of that, we will assess the 2013 Annual Aircraft Noise Contours (AANC) and 2013 monitoring results against the new District Plan noise contours in the Waimakariri and Selwyn District Plans and the old District Plan noise contours in the Christchurch City District Plan.

Rule 11 - 1.2.4.2 sets out the airport's obligation to provide annual calculations of the aircraft noise levels and the results of noise measurements where necessary.

#### "1.2.4.2 Aircraft noise monitoring

CIAL shall annually provide to the Council's Environmental Services Manager the result of calculations based upon monitored aircraft movements for the preceding year and the known noise characteristics of those aircraft. These calculations will be performed by a person with appropriate qualifications and experience in airport noise modelling and acoustic assessments. The provided result shall be verified by noise measurements and shall be in the form of a 65 dBA  $L_{dn}$  contour representing the noise created by aircraft operations over that year (other than movements of a kind excluded in the Aircraft Noise Rule 1.3.5) superimposed upon a copy of the plan forming Appendix 3 to Part II of this Plan. The measurement of aircraft sound exposure and the resultant derivation of a 65 dBA  $L_{dn}$  shall be in accordance with NZS 6805:1992."

# 2.0 ANNUAL AIRCRAFT NOISE CONTOURS

To ensure compliance is fully assessed, 2013 Annual Aircraft Noise Contours have been calculated based on the average daily movements over the busiest three months. In previous years another contour has been calculated which represents the busiest three months on Runway 29.

The purpose of calculating noise contours for the busiest three months on Runway 29 is to assess compliance for the period of time when the north-west winds are prevalent and aircraft utilise Runway 29 more than usual.

Although this is not expressly required by the District Plan, we believe that it is necessary as it provides a worst case scenario when confirming noise levels over the City within the 65 dB L<sub>dn</sub> contours as identified in the city Plan (Volume 3, Part 2, Appendix 3 - 65 dB L<sub>dn</sub> Airport Noise Monitoring Contour - CIAL).

A diagram of the Christchurch Airport runway system is included as Appendix A for reference.

# 2.1 INM Inputs

The both sets of 2013 annual contours have been calculated using the INM version 6.0c which is the same version used to prepare the existing Christchurch City District Plan noise contours.

A record of the aircraft activity for 2013 has been provided by CIAL for input in to the INM in the form of monthly movements by aircraft type, operation, runway and time of day. This data is recorded by Airways Corporation and includes all movements of aircraft that are fitted with a transponder. As some general aviation (GA) aircraft do not have transponders, not all GA movements are accounted for.

Noise from these light aircraft does not contribute significantly in terms of noise levels within the 65 dB  $L_{dn}$  contour. For that reason, the nature and frequency of GA flights on the overall noise exposure would not affect the location of the 65 dB  $L_{dn}$  noise contour significantly. The effect of general aviation aircraft on the overall noise exposure and compliance with the District Plan noise contours is identified in Appendix C.

MDA has analysed the movement data and determined that the busiest three consecutive months were October, November and December. The busiest three months for Runway 29 were September, October, November.

The annualised total movements for both modelled scenarios are shown in Table 1 as well as a breakdown of the annualised day and night time movements. The number of night time movements is relevant as night time activity has an associated + ten decibel adjustment. A breakdown of the average daily aircraft movements by aircraft type and runway for each of the modelled scenarios is included as Appendix B.

	Busiest 3 Months	Busiest 3 Months RW 29
Annualised Total Movements	91800	90756
Annualised Day Time Movements	77932	77244
Annualised Night Time Movements	13868	13512

#### Table 1: Summary of Modelled Aircraft Movements

The aircraft movement data provided by CIAL does not contain explicit runway usage data, rather the runway is defined as either the main runway (02/20) or the crosswind runway (11/29). Historical records of aircraft movements at the airport have been analysed to determine the predominant runway usage at the airport. Based on these records the historical runway usage is as follows:

Main Runway:	RW 02 = 64 %
	RW 20 = 36%
Crosswind Runway:	RW11 = 0%
	RW 29 = 100%

In the model, aircraft movements have been distributed across flight tracks which were developed in 2007 during the review of the airport noise boundaries. The contour outcomes of the 2007 review are implemented in Change 1 to the Regional Policy Statement. It is noted that for the purpose of modelling the location of the 65 dB L<sub>dn</sub> contour, the flight track details beyond 4 km from the runway are irrelevant as the contour does not extend further than this. Therefore the approach taken is considered to be robust, valid and appropriate.

# 2.2 Calculated Contours

The calculated 65 dB  $L_{dn}$  contour for 2013 activity, as described above, is shown in Figure 1 for the busiest 3 months and Figure 2 for the busiest 3 months on runway 29, below, both compared with the Waimakariri/Selwyn District Plan and Christchurch City District Plan 65 dB  $L_{dn}$  noise contours.

There is a small area close to the RW29 threshold where figure 2 shows a slight exceedance of the Waimakariri/Selwyn District Plan contour. This contour is expected to be adopted by Christchurch city following their plan review, but is not currently used for airport compliance purposes. Further, the area is directly

adjacent to the runway, is minor in extent and entirely on airport operational land. Therefore this impact is not considered significant.

The applicable Christchurch City District Plan 65 dB  $L_{dn}$  noise contour is not exceeded. Accordingly, this report identified compliance with the requirements of Rule 11-1.3.6 'Aircraft Noise'.

Figure 1: Noise from Aircraft Operations 2013 Compared with City Plan Limit

Figure 2: Noise from Aircraft Operations 2013 Runway 29 use Compared with City Plan Limit

# 3.0 MONITORED NOISE LEVELS

# 3.1 Site Locations

Marshall Day Acoustics airport noise monitor was located at Shipley Farm, Christchurch from 1 January 2013 to 21 January 2013 for the purpose of measuring  $L_{dn}$  noise levels from aircraft operations. The site is approximately 2.2 kilometres from the end of the main runway (RWY 20) and 200m on sideline to the north. The site location relative to the Waimakariri/Selwyn District and Christchurch City District Plan 65 dB  $L_{dn}$  noise contour is shown in Figure 1 and Figure 2.

Noise levels were also measured at 454 Wairakei Road in response to a complaint received regarding engine testing noise, also shown on Figure 1 and 2.

# 3.2 Airport Noise Monitoring Equipment

Noise monitoring was carried out in general accordance with New Zealand Standard NZS 6805:1992 "Airport Noise Management and Land Use Planning". The Marshall Day Acoustics airport noise monitor consists of a Norsonic 1225 sound level meter with an outdoor microphone kit. Data is stored on a memory card and downloaded through the Noise and Weather website. The noise monitoring equipment and set-up is shown below.

# Figure 3: Noise Monitor Set-up

The system normally uses the aircraft identification software in post processing to isolate any events with aircraft characteristics.

The analysis software allows calculations to be undertaken over a wide range of parameters, and provides graphical noise level traces that can be used in the analysis process. Figure 5 shows a typical screenshot of the software analysis module.

#### Figure 5: Analysis Software Screenshot

In this case the software was not able to be used to distinguish individual noise events so the overall community noise levels have been analysed from the raw noise measurement data. Because this data represents is the total noise level measured at the site; it includes *all* aircraft events that occurred as well as extraneous noise sources. If the measured noise level is lower than the airport noise limit, then it can be said that compliance has occurred.

# 3.3 Monitoring Results

A total of 20 full days of data were recorded. The average, maximum and minimum measured noise levels are shown in Table 2.

Table 2: Summary of Noise Me	easurement Results
------------------------------	--------------------

	Measured Noise Levels (dB L <sub>dn</sub> )
Minimum	58
Maximum	63
Average	61

The measured noise level is also shown graphically illustrated in Figure 3.

We consider that this data is sufficient to provide a reliable assessment of the Airport's operating noise level. This is because there is only a small and insignificant variability in measured noise levels over the monitoring period, suggesting that the monitoring is accurate.

Based on the Christchurch City District Plan 65 dB  $L_{dn}$  noise contour as shown on Figure 1 and 2, the noise level at the monitoring site is approximately 2 decibels below the level at the Christchurch City District Plan 65 dB Ldn noise contour. For the Waimakariri/Selwyn District Plan contour the noise level at the monitoring site is also approximately 3 decibels below the level at the Waimakariri/Selwyn District Plan 65 dB Ldn noise contour.

Further, the measured noise levels are consistent with the predicted noise levels of Figure 1, verifying that the predictions are an accurate representation of noise levels received in the community.

Based on the above, the monitoring results demonstrate that noise from aircraft operations during the monitoring period comfortably complied with the relevant noise limit.

Noise monitoring was also undertaken at 454 Wairakei Road and a property on Guthries Road in response to complaints relating to engine testing and general aircraft activity respectively (refer s4.1 and s5.1).

# 4.0 ENGINE TESTING

The Noise Management Plan discusses the methods used to manage noise from engine testing at Christchurch Airport. The Noise Management Plan States:

*"3.0 Engine Testing* 

Under the by laws and the Airside operations Agreement details of each night-time engine testing event are recorded by the aircraft operator and forwarded to CIAL. CIAL will record the details of each event in a purpose made engine testing noise monitoring application. This software will be used to calculate noise levels in the wider community resulting from night time 'on wing' engine testing. The noise levels received at the most affected dwellings shall be calculated and monitored over a period of not less than 3 months for the purpose of carrying out an assessment of engine testing noise effects. Following the assessment of noise effects, consideration will be given to developing additional or alternative controls on engine testing and land use management should the outcome of the assessment signal that this is appropriate. The target completion date of the assessment of engine testing noise effects is March 2014."

The software referred to in the NMP has been developed by MDA over the last year and is now being used to collect and analyse engine testing data. The MDA software (Engine Testing Monitoring Software - ETMS) is being used to calculate and assess the noise levels emitted over the period November 2010 to the present time (where ANZL records are available).

These historical noise emissions will be compared with appropriate engine testing noise limits. At present there is no actual requirement in the Christchurch by-law regarding engine testing noise levels. This is the reason that the software is being used in reviewing the calculated noise levels in relation to controls used elsewhere in NZ.

A report will be prepared on the results in due course, including an opinion on the magnitude of the noise exposure. It intended to pause at this point to allow discussions between CIAL and ANZL over the outcome of the study and to determine what, if any, further work in determining appropriate controls is required. The report will include a comparison of the historical noise emissions with various noise controls and an opinion on the noise exposure for residents surrounding the airport.

Engine testing noise control and actual calculated noise levels are anticipated to be presented in this specific report, and are likely to be reported in this Noise Monitoring Report from 2014 onwards.

# 4.1 Measured Engine Testing Noise Levels

As a result of noise complaints from a resident at 454 Wairakei Road a noise investigation was carried out using noise measurements and analysis. The aim was to identify aircraft engine testing noise events that may have given rise to the complaint. In summary the results show that although engine testing noise levels would be audible at the house (based on the actual measured noise level and the characteristics of the noise), engine testing noise is acceptable in the context of the existing environment and the overall noise level.

Full details are presented in Appendix D.

# 5.0 COMPLAINTS

Noise Complaints are occasionally received as a result of both general airport operations and specifically related to engine testing. CIAL currently investigate complaints in the following manner:

The CIA Noise Complaints Procedure provides individuals with the ability to express, and have recorded, their concerns about aviation noise (activities) or to ask questions regarding noise at CIA.

Noise complaints may be made by calling the CIAL Integrated Operation Centre (IOC) office which is manned 24 hours a day (on phone 353 7777). IOC staff document noise complaints by obtaining information from the caller about the nature of the complaint, time of the occurrence, location of callers residence and the activity that caused disturbance. This information is used to determine the probable activity that was responsible for the complaint.

A follow up phone call will be made followed by a written response / e-mail if requested by the caller detailing the complaint and details of the activity responsible, the meteorological conditions and the runway in use at the time of the disturbance. A notice of action taken by CIAL in respect of the complaint will be included. Typically it will take CIAL staff up to 2 days to make a follow up phone call and up to 7 days to respond in writing if where required

The following is a summary of noise complaints received in 2013:

Complaints TypeNumberGeneral Aviation (GA)4Low flying jets7Engine testing3

# 5.1 Specific Complaint investigation – Guthries Road

As a result of noise complaints from a resident at 171 Guthries Road a noise logger was installed. The aim was to identify aircraft noise events that were noticeably louder in this vicinity than typical events.

Overall it was concluded that measured aircraft noise levels were not excessive and generally were comparable to nearby road traffic noise levels. Full details are presented in Appendix D.

# 6.0 CONCLUSION

Noise contours have been calculated and in-field monitoring carried out to establish whether noise from aircraft operations at Christchurch International Airport during 2013 complied with the Waimakariri, Selwyn and Christchurch City District Plan 65 dB  $L_{dn}$  noise contour limit. Both the contouring exercise and the noise monitoring results confirm that noise from aircraft operations in 2013 comfortably complied with the 65 dB  $L_{dn}$  limit.

Engine testing noise levels are currently being assessed and will be reported on in due course.

# **APPENDIX A: CHRISTCHURCH AIRPORT RUNWAY VECTORS**

**Runway 02** refers to operations using the main runway with a heading of 20 degrees from true north i.e. arrivals from the south west landing in a north easterly direction and departures towards the north east.

**Runway 20** refers to operations using the main runway with a heading of 200 degrees from true north i.e. arrivals from the north east landing in a south westerly direction and departures towards the south west.

**Runway 29** refers to operations using the crosswind runway with a heading of 290 degrees from true north i.e. arrivals from the south east landing in a north westerly direction and departures towards the north west.

#### APPENDIX C: THE EFFECT OF GA ACTIVITY ON THE NOISE CONTOURS

General Aviation (GA) aircraft are light piston powered propeller driven aircraft typically operated by small businesses, private operators and aero club members. There is a considerable number of GA aircraft operating from Christchurch Airport but the noise emission of a GA aircraft is significantly lower than a commercial jet. Neither the existing City Plan noise boundaries nor the recently developed 'Expert Panel' noise boundaries include GA activity in the modelling. The Expert Panel agreed that the contribution of GA aircraft to the Airport's noise contours was insignificant and therefore it was not necessary to include this activity in the modelling.

To validate this assertion, the noise contours for the busiest three months in 2008 were calculated both with and without GA activity. The actual aircraft type for each GA movement was not identified in the available records therefore the calculations were based on the noisier GA aircraft types operating at the airport. The inclusion of GA in the model resulted in an increase of approximately 0.1 dB in Ldn which is considered to be a negligible change. Due to the small contribution to overall noise from the GA aircraft, it is considered reasonable to exclude this activity from the INM calculations.

The effect that GA activity has on the noise contours in the future will depend on the ratio of GA movements to large commercial aircraft movements. To monitor any significant change in this ratio, the table below lists the annualised busiest three months of airport operations by aircraft category. Each year the table will be updated in order to develop a historical record and highlight any significant changes in GA activity ratios.

	Jet	Turbo-Prop	<b>General Aviation</b>
2008	47,000	40,000	30,000
2009	39,000	40,000	54,000
2010	37,000	40,000	47,000
2011	39,000	35,000	44,000
2012	42,000	44,000	42,000
2013	36,000	51,000	37,000

#### Annualised Busiest Three Months of Aircraft Movements by Aircraft Category

Note: Figures are rounded to the nearest 1000 movements and are not exact

#### APPENDIX D: COMPLAINTS INVESTIGATION AND CIAL RESPONSE

Two detailed complaints investigations were carried out in 2013, one related to general aircraft activity, and one to engine testing noise. Each of which is summarised in this section.

#### **General Noise Complaint – Guthries Road**

As a result of noise complaints from a resident at 171 Guthries Road a noise logger was installed. The aim was to identify aircraft noise events that were noticeably louder in this vicinity than typical events. The nature of the complaints received suggests that the perceived noise may be due to aircraft flying abnormally and unreasonably low.

This site is a considerable distance outside the CIAL outer control boundary (50 dB  $L_{dn}$ ), as shown in the District Plan. As the complaints received relate to individual aircraft being perceived as loud and intrusive the maximum sound pressure level ( $L_{AFmax}$ ) parameter is used.

# Results

The loudest event identified during the survey was 76 dB  $L_{AFmax}$ . This was likely to be a helicopter flying either directly overhead the logger or nearby. A number of ATR, Q300 or B1900D aircraft near the Guthries Road area were identified. These aircraft typically resulted in a maximum sound level of approximately 55 dB  $L_{AFmax}$ , although occasional maximum noise levels of around 60 dB  $L_{AFmax}$  were also measured.

A number of additional jet aircraft events were identified by audio analysis. These were not logged by Airways as having entered the Guthries Road area. It is likely that these aircraft were either taking off from, or approaching the main runway at CIAL. Typical maximum sound levels for these events were approximately 63 dB L<sub>AFmax</sub>.

A number of other smaller aircraft were also recorded on audio but not logged by Airways. These appear to be small propeller driven GA aircraft. Typical maximum sound levels for these events were 65 dB L<sub>AFmax</sub>.

The measurements also show a large number of noise events that are not generated by aircraft. Most significant amongst these is vehicle traffic on Guthries Road and Marshlands Road. The maximum sound levels for these events were typically 55-65 dB L<sub>AFmax</sub>. These are very similar to the aircraft noise levels. Overall, for noise levels above 55 dB L<sub>AFmax</sub>, the number of road vehicle events is significantly larger than the number of aircraft events.

# Conclusions

The only aircraft noise event that was markedly louder than other aircraft events was a helicopter flying VFR either directly overhead or close by. Commercial

aircraft associated with CIAL (both turbo-prop and jet) fell within a reasonably narrow range of noise levels with no evidence that any one event was likely to be the result of aircraft flying abnormally low.

Despite extended periods of southerly winds over the monitoring period (the conditions most likely to result in commercial aircraft overflying Guthries Road) there was no evidence of aircraft associated with CIAL generating abnormally high or unreasonable noise levels.

The maximum noise levels generated by aircraft events associated with CIAL were comparable to that generated by vehicle traffic on Guthries and Marshlands Roads. These noise levels are typical of that experienced by many thousands of Christchurch residents on a daily basis and over a wide area of the City as a result of both road and aircraft traffic.

#### Engine Testing Noise Complaint – 454 Wairakei Road

As a result of noise complaints from a resident at 454 Wairakei Road a noise investigation was carried out using noise measurements and engine testing ground run analysis. The aim was to identify aircraft engine testing noise events that may have given rise to the complaints. Noise measurements were undertaken on-site between 18 October and 8 November 2013.

A comparison was made between records of engine testing activity (prepared by the engine testing ground run engineers and compiled by CIAL) and measured noise levels at the site.

This has been undertaken using the CIAL Engine Testing Monitoring Software (ETMS). MDA has previously developed the ETMS that will be used in the future to undertake engine testing noise assessment. The software comprises two aspects;

ETMS Inputs –Aircraft engineers performing engine tests input details of the type of test, engine power settings, duration, aircraft location and orientation into the software database.

ETMS Outputs – Noise levels are calculated for 16 key receiver locations based on the use of the input data (above). These receivers have been chosen as the reasonable worst case locations relative to engine testing noise levels.

For this complaint investigation, the input data has been extracted to examine correlation between actual engine test events and noise levels as measured at 454 Wairakei Road.

Measured engine testing noise levels for all identified events ranged between 41 – 58 dB  $L_{Aeq}$  for the duration of the event. When compared with the typical measured background noise level at the residence, it is noted that these engine testing noise levels would be noticeable and that some events would also be clearly audible at night.

The testing of aircraft engines is an activity which is vital to the operational viability of a commercial airport, and like aircraft movements, it cannot normally be accommodated within standard district plan noise rules. As such engine testing often requires a specific noise assessment. The approach adopted here is generally in line with that used at other New Zealand airports for engine testing. The assessment uses the L<sub>dn</sub> metric measured over the daytime and night-time periods.

The measured noise level from each correlated engine test event has been used to calculate the daily noise exposure from engine testing noise at the site. The data recorded at the noise monitor has also been analysed more simply to compare the overall noise exposure at the residence (ambient  $L_{dn}$ ; including road traffic noise, residential activity etc) with engine testing noise alone.

Day	Engine testing noise level (dB L <sub>dn</sub> )	Community noise level (dB L <sub>dn</sub> )
17 October 2013	47	55 <sup>1</sup>
18 October 2013	45	57
19 October 2013	37	55
20 October 2013	40	55
21 October 2013	48	58
22 October 2013	46	57
24 October 2013	46	57
25 October 2013	40	58
26 October 2013	48	57
4 November 2013	48	55 <sup>1</sup>
6 November 2013	48	58
7 November 2013	39	57
8 November 2013	55	58
9 November 2013	39	58

Calculated noise exposure levels are shown in Table D2 below:

<sup>1</sup>Community noise levels calculated for these days on the basis of an estimate of night-time contribution. Noise levels were not measured during the night on these days because of equipment issues. Noise levels were estimated based on night-time noise levels occurring on other days in the monitoring period

Overall, this community noise level is in the normal range expected for a residential noise environment. It is also observed that engine testing noise exposure is significantly less than the community ambient noise at this location.

The results show that although engine testing noise levels would be audible at the house for short durations (based on the actual measured noise level and the characteristics of the noise), the engine testing noise is regarded as acceptable in the context of the overall ambient noise level.
